Knosp grade and incomplete resection across two independent pituitary cohorts
Secondary analysis of public data (STROBE) — testing reproducibility of association, not validating a prediction model
TAIWAN (index)
103 -> 100 analysed
Knosp · MRI residual
LOS · previous surgery
SPAIN (replication)
100 analysed
Knosp · volumetric GTR
LOS · previous surgery
Shared specification: ordinal Knosp + previous surgery; Firth logistic; harmonisation & leakage check
PRIMARY — incomplete resection
direction reproduced across cohorts
absolute risk NOT shown transportable
EXPLORATORY — length of stay
Knosp × cohort interaction
influence of two extreme stays
Reproducible association direction ≠ transportable absolute risk ≠ stable LOS association
